

Substitute Abstract

A foamer dispenser includes a dual pump for separately sucking, pressurizing and pressure-feeding the contents within a container and ambient air; a head having a passage; and a foaming element disposed within the passage of the head. The foaming element includes a jet ring having an inlet opening with an opening area narrower than that of the passage of the head, a tubular body with an opening area larger than that of the inlet opening, and a mesh disposed to face to the opening. The mesh has a number of fine holes to be contacted with the contents supplied from the opening to allow a part of the contents to pass through the mesh. The mesh has an opening diameter which is 2.0 to 3.5 times as large as an opening diameter at the inlet opening of the jet ring.
